

25-01-2026

Agenda:

- String methods •
- while loop •
- Functions •
- Function arguments •

String methods

"Hello".
 - strip()
 - lstrip()
 - rstrip()

developer → standard → find ('M') → -5

Loops:

for

→ iterate over a sequence
 of elements

ex. for i in [1, 2, 3]:

→ we already know how many iterations loops is going to take.

while

→ repeat a block of code until certain condition is true

ex. while condition:

condition → understand python

while condition:

jump to next topic

Syntax: `while condition :`

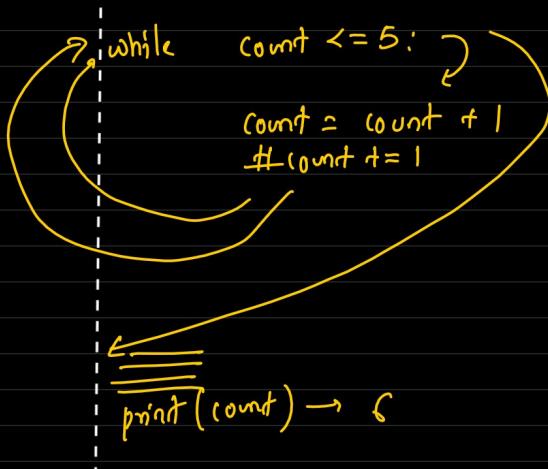

`do something`

Example:

`count = 0`

keep adding +1 to the count until it is smaller than
or equal to 5.

`if count <= 5`

`count = 0`
`cond: 0 <= 5 → true`
`count = 1`
`cond: 1 <= 5`
`count = 2`
`cond: 2 <= 5`
`count = 3`
`cond: 3 <= 5`
`count = 4`
`cond: 4 <= 5`
`count = 5`
`cond: 5 <= 5`
`count = 6`
`cond: 6 <= 5`

dry run

`hello != hello → fall`
`user_input = ""`
`while user_input != "hello":`
 `user_input = input("Enter your input")`
 `print(user_input)`
`print("after while loop")`

`hello`
`User_input`
`input()`
`print('hello')`
`print("after while loop")`

control flow :

`for condition :`
`→ 100 times`

`100 values`

for name in names:
 if name == 'monal': → true
 continue
 name = name.capitalize()
 name = name.upper()
 print(name)

if 'a' ≥ 'monal':
 Continue
 → something
 → something
 → something

for name in names:
 if name == 'monal':
 break
 name = name.capitalize()
 name = name.upper()
 print(name)

break → Terminate the loop

continue → Skip the current iteration

'a' ≥ 'monal' → run below
 'b' ≥ 'monal' → — || —
 'mona' ≥ 'monal' → True
 ↓
 break
 ↓
 come out of loop

Function: — is a named, reusable block of code,

→ used for a specific task.

examples : print() print() ≡ reusable
 : type() print()
 ↓
 pre-defined function print the output in terminal / screen.

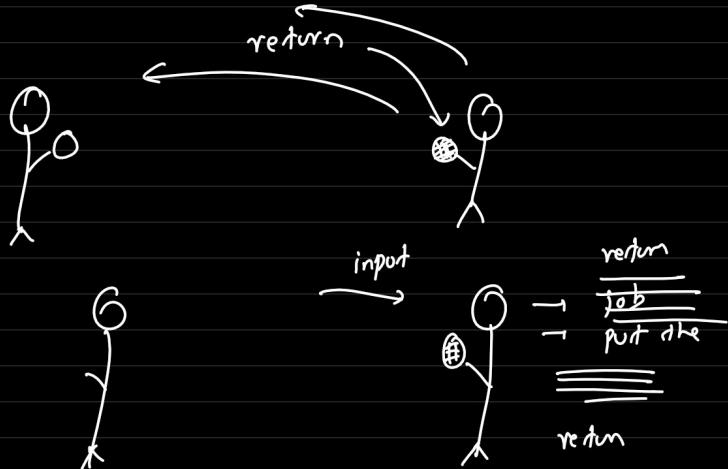

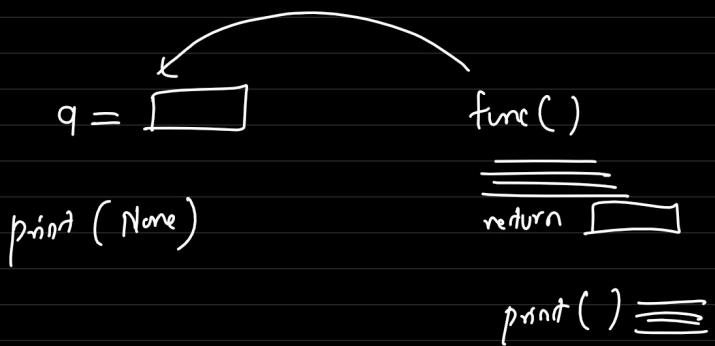

User-defined function:

Syntax: def name-of-function ():
 do something

def print ():
 ≡ predefined function

function → our_custom_string_cleaner → doing some job
 ↓
 print → clean version of string
 ↗ cleaning the string inside it

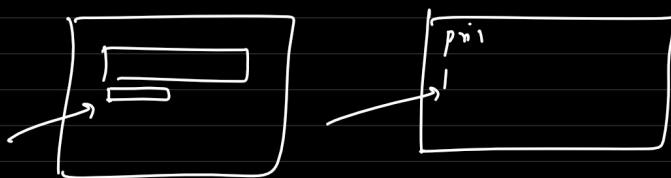

p.) we want to get cleaned string .

`print(3) → OS → [3]`
 $a \approx 3$
 \vdots
 $a + 1$
`print(a) → [4]`

↑ see the output

Terminal

$l = [200, 100, 2, 3]$

$\text{sorted}(l) \rightarrow$ sort the given list & store
the new sorted list in a variable
 \rightarrow return the new variable.

$l = \text{sorted}(l)$ None

$l = [2, 3, 100, 200]$

when we don't want updated value

function → job
→ return None
→ return value

when we want update value

```
def add_dummy():
    name = input("Enter your name : ")
    print("hello", name, "Greeting from krish naik academy.")
```

return_value = add_dummy() input "Hello" --- if
print(return_value)

return_value ← None ← add_dummy()

method
certain class
split
 $lol.split() \rightarrow$ not

function → returns something → nothing → None
 value →

P.J

we want to create reusable code that will
 take input from user a) a number &
 subtract. Once calculate return that value.
